Public Case Study - Website Enquiry Qualification in n8n

Local portfolio prototype. Fictional leads only. No client deployment or measured business outcome.

The problem

Small B2B service teams often read website enquiries manually, decide which ones look promising, and copy them into a CRM. Repeated submissions, incomplete fields, uncertain qualification, and failed steps make that process hard to trust. This demo explores a clearer route from form submission to a reviewable record.

The build

I built a visual n8n workflow that receives a webhook enquiry, normalizes and validates its fields, and checks the combination of normalized email and company before qualification. A real Google Gemini call returns structured fit, score, confidence, reason, and missing-information fields. The workflow independently checks that response instead of trusting the model output. Low-confidence, incomplete, or invalid results go to human review.

Qualified leads are recorded in **n8n Data Table used as a CRM-style persistence layer in this demo**. A high-value notification is recorded as a **mock**, and a follow-up is kept as `draft_only`; no email is sent. Failed stages are visible and can be retried within the demonstrated workflow.

Evidence

The local real-LLM version passed **10/10 test scenarios** using fictional data. The scenarios included high-fit and incomplete enquiries, invalid input, a repeat submission before a second AI call, malformed model output, simulated service failures, and retry. The destination table was checked for duplicate lead IDs. These results demonstrate the tested local paths, not a guarantee for simultaneous submissions: the n8n version has no enterprise exactly-once claim. A separate Node.js simulator tested concurrent submissions, and that result is **not** attributed to n8n.

Limits

There is no live customer traffic, external CRM connection, real sent notification, or measured ROI. The workflow ran locally. A client engagement would require their own accounts, a written scope, privacy review, integration-specific tests, and acceptance before use with real data.

Detailed local test evidence is available on request.
